

gtmos — Concept Note

2026-07-13 · self-hosted GTM operating system · gtmos-landing.vercel.app

In one line

gtmos shows a GTM team where they are losing money — a deterministic CRM-integrity and deal-funnel audit that runs entirely on the customer's own machine. Their CRM data never leaves their infrastructure.

The problem

Every revenue team is quietly bleeding money in three places: dead and duplicated CRM records nobody reaches, deals that stall silently in the pipeline, and follow-ups that arrive late. The existing tools that could measure this all share one requirement — you hand over API access and your entire contact and deal database flows into their cloud. For a founder in a regulated, security-conscious, or data-sensitive business, that is a non-starter. So the leak goes unmeasured.

What we built

A working product, not a prototype. gtmos v0.3.0:

- **audit** — a deterministic CRM Integrity Score across five weighted dimensions (completeness, validity, freshness, ownership, consistency), two-tier duplicate detection (exact-email, then fuzzy name+company), and a published dollar-leak model. No LLM touches any score; every number is reproducible from the same input.
- **funnel** — deal-stage revenue-leak analysis: closed-lost value plus half of stalled open-deal value, with median imputation for unvalued deals.
- **today / weekly** — the operating loop: a role-aware daily checklist (stalled deals, due touches, audit grade) ordered by dollars at risk, and a weekly leak review.
- **plays** — four built-in signal plays (post-merger, new-RevOps-hire, hiring-spree, compliance-wall) as multi-touch sequences.
- **serve** — a local web dashboard for non-technical teammates, bound to 127.0.0.1, read-only.
- **quickstart / doctor** — one command from a HubSpot token to the first leak number; a security/environment preflight.

Engineering posture: Python 3.11+, standard library only, zero external dependencies. 178 automated tests. All LLM calls route through a single audited chokepoint that writes a receipt for every call — enforced by a static check that fails the build if any other code path shells out to a model. The scoring engine is deterministic pure functions, independently portable.

The wedge

Zero-egress is the differentiator, and it is structural. The only two systems gtmos ever contacts outside the customer's machine are their own HubSpot API (via a token they hold) and their own local model CLI. The scoring engine never makes a network call.

This is the one thing cloud-native competitors cannot copy. A platform whose business model is “pour your CRM into our cloud” or “replace your system of record with ours” cannot offer “your data never leaves your machine” — it is the opposite of their architecture. gtmOS does not replace the CRM; it audits the one the customer already trusts. Lower switching cost, and a defensible position in the exact segment the cloud incumbents structurally cannot serve.

How it works

1. Install locally (`pip install -e .`); point it at a HubSpot token or an offline export.
2. `quickstart` runs the audit and funnel and returns a single headline: “*you are losing \$X.*”
3. The team runs today each morning against the same local data; weekly refreshes the leak review.

Deterministic scores mean the number is checkable, not a black box. The methodology is published in full.

Status (honest)

- Product: **built and shipped**, v0.3.0, source-available, 178 tests passing.
- Landing page: **live**.
- Sample output: a full audit on 500 synthetic records (Grade C, dollar-leak estimate) is downloadable today.
- Revenue: **pre-revenue**. The go-to-market motion — a free, high-touch trial that shows a founder their real leak number, converting to a paid audit — is designed and about to be tested with a first set of founders. No paying customers yet; this note does not claim any.

The model (direction, not yet proven)

A ladder, funded by services, with the tool as the durable asset:

- **Free trial** — show the leak number; the moment of proof.
- **Productized audit** — a fixed-price CRM Integrity Audit, delivered by us.
- **Operator layer** — trained operators (the “GTM engineer” role Clay created a market for) run the loops inside client companies. We intend to supply that operator layer, not just the tool.
- **License** — an annual per-workspace license for teams who run it themselves, gated on proven willingness-to-pay.

The tool is what compounds and what is fundable or acquirable; the service is the cash engine and the proof.

What is portable

The deterministic engine — scoring, deduplication, and the leak model — is self-contained pure logic with a full test suite, straightforwardly re-implementable in any stack. The value is the methodology and the zero-egress architecture, not the language it currently ships in.

What's next

- Run the trial with the first founders; measure conversion from “sees the leak” to “pays for the audit.”
 - Ship an in-browser version of the audit engine — paste an export, score it client-side, nothing leaves the tab — as the most direct possible demonstration of the zero-egress claim.
 - Decide the primary path (independent growth vs. partnership/acquisition) on the evidence the trial produces, not ahead of it.
-
